### LIGHTED SWITCH DEVICE

### BACKGROUND OF THE INVENTION

- 1. Field of the Invention
- The present invention relates to a lighted switch device used in, for example, a control section of a vehicle-installed air conditioner, and, more particularly, to means for preventing undesirable leakage of light from some portion.
  - 2. Description of the Related Art
- As shown in Figs. 4 and 5, a related lighted switch device for a vehicle-installed air conditioner comprises one rotary knob (first operating knob) 1, four push knobs (second operating knobs) 2, 3, 4, and 5 disposed around the rotary knob 1, a case 6 having a front plate 6a to which the rotary knob 1 and the push knobs 2, 3, 4, and 5 are mounted, a rotation detector 8 mounted to a wiring board 7 and accommodated in the case 6, switch elements 9, LEDs 10 (light-emitting diodes serving as light sources), and an annular light conductor 11 for transmitting exiting light 10a
- 20 from the LEDs 10 to the outer peripheral portion of the rotary knob 1.

comprises an annular light-shielding member 13, disposed at a portion of the case 6 where the light conductor 11 is

25 disposed, for preventing light from leaking into gaps 12 formed between pairs of adjacent push knobs, that is, between the push knobs 2 and 3, between the push knobs 3 and 4, between the push knobs 4 and 5, and between the push knobs 5

This type of related lighted switch device further

and 2.

In the related lighted switch device, since the annular light-shielding member 13 is disposed around the annular light conductor 11, it is possible to prevent light from leaking into the gaps 12, disposed between the respective pairs of adjacent push knobs, from the light conductor 11, so that the lighted switch device can be easily seen.

In the related lighted switch device, since the lightshielding member 13, which is formed at the case 6, is disposed in a gap 14 between the rotary knob 1 and the push 10 knobs 2 to 5, the light-shielding member 13 is viewed concentrically with the light conductor 11 in plan view of the lighted switch device. Therefore, the related lighted switch device is not designed well. In addition, the gap 14 Therefore, also for this reason, the 15 is inevitably large. related lighted switch device is not designed well, thereby increasing the size of the switch device. Further, since the light-shielding member 13 is formed at the case 6, a die used for injection molding of the case 6 is large and complicated. Therefore, the lighted switch device, which is a product, is high in cost.

## SUMMARY OF THE INVENTION

Accordingly, the present invention is achieved to
25 overcome the aforementioned related problems, and has as its
object the provision of a small low-cost lighted switch
device which is designed well.

To this end, according to a basic form of the present

invention, there is provided a lighted switch device comprising a first operating knob; a plurality of second operating knobs comprising a pair of adjacent second operating knobs and disposed around the first operating knob; a case having a front plate for mounting the first operating knob and the plurality of second operating knobs; a light source accommodated in the case; a light conductor for transmitting exiting light from the light source to an outer peripheral portion of the first operating knob; and a light-shielding member, which is disposed at one of the pair of adjacent second operating knobs and which protrudes in a gap disposed between the pair of adjacent second operating knobs, for preventing light from leaking into the gap from the light conductor.

In this way, when light is prevented from leaking into 15 the gap from the light conductor by making the lightshielding member, which is disposed at one of the pair of second operating knobs, protrude into the gap disposed between the pair of adjacent second operating knobs, the size 20 of the gap is small, which is, in general, approximately 1 mm. Therefore, the light-shielding member is only slightly seen in plan view of the lighted switch device, so that the design of the lighted switch device can be improved. In addition, it is not necessary to form the light-shielding member at the case, and a gap between the first operating knob and the 25 second operating knobs can be reduced in size. also for this reason, the design of the lighted switch device can be improved, thereby reducing the size of the lighted

switch device. Further, since it is not necessary to form the light-shielding member at the case, it is possible to simplify and reduce the size of a die used for injection molding of the case, and, thus, to reduce the cost of the lighted switch device, which is a product.

In the basic form, the other of the pair of second operating knobs has a recess for inserting an end of the light-shielding member.

In this way, when the light-shielding member is disposed at one of the pair of adjacent second operating knobs, and a 10 recess for inserting an end of the light-shielding member is formed in the other second operating knob, it is possible to more reliably achieve a light-shielding operation by the light-shielding member compared to the case in which an end portion of the light-shielding member, which is formed at one 15 of the pair of adjacent second operating knobs, is disposed close to a side surface of the other second operating knob. Therefore, it is possible to prevent light from leaking into the gap between the pair of adjacent second operating knobs, 20 so that the design of the lighted switch device can be further improved.

In the basic form, the first operating knob may be a rotary knob, and the plurality of second operating knobs may be push knobs.

In this way, when the first operating knob is a rotary knob, and the second operating knobs are push knobs, it is possible to construct one switch device by a combination of operating knobs operated by different methods. Therefore, by

using the rotary knob and the push knobs according to functions, the operability of the switch device can be enhanced. For example, when the push knobs are used for selecting functions, such as automatic-manual switching of a vehicle-installed air conditioner, in-vehicle-defrosting switching, temperature setting, and air volume setting, and when the rotary knob is used for temperature adjustment and air volume adjustment, it is possible to match the operational feel of the knobs and the feel of selecting the respective functions and adjusting the functions. Therefore, the lighted switch device, which is used in a control section of the vehicle-installed air conditioner, provides good operational feel.

### 15 BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a plan view of the main portion of a switch device of an embodiment of the present invention;

Fig. 2 is a sectional view of the main portion of the structure of a portion of the switch device of the embodiment of the present invention where light-shielding members are formed;

Fig. 3 is a sectional view taken along line III-III of
Fig. 1;

Fig. 4 is a plan view of the main portion of a related 25 switch device; and

Fig. 5 is a sectional view taken along line V-V of Fig. 4.

### DESCRIPTION OF THE PREFERRED EMBODIMENT

Hereunder, a lighted switch device of an embodiment of the present invention will be described with reference to Figs. 1 to 3.

As shown in Figs. 1 to 3, the lighted switch device of the embodiment has basically the same structure as the related lighted switch device. It comprises one rotary knob (first operating knob) 1, four push knobs (second operating knobs) 2, 3, 4, and 5 disposed around the rotary knob 1, a case 6 having a front plate 6a to which the rotary knob 1 and the push knobs 2, 3, 4, and 5 are mounted, a rotation detector 8 mounted to a wiring board 7 and accommodated in the case 6, switch elements 9, LEDs 10 (light-emitting diodes serving as light sources), and an annular light conductor 11 for transmitting exiting light 10a from the LEDs 10 to the outer peripheral portion of the rotary knob 1.

The rotary knob 1 is injection molded out of resin and into the shape of a cap including a top surface 1a and a cylindrical portion 1b, and is rotatably mounted to the front 20 plate 6a of the case 6. In order to make it possible for an operator to see the function of the rotary knob 1, a character, a pictorial character, etc., which is illuminated by the exiting light 10a from the LEDs 10, may be indicated on the top surface 1a of the rotary knob 1.

25 The push knobs 2, 3, 4, and 5 are injection molded out of resin and into the shape of a tray, and are mounted to the front plate 6a of the case 6 so that they can be pushed. The push knob 2 has a push surface 2a and a flange 2b. The push

knob 3 has a push surface 3a and a flange 3b. The push knob 4 has a push surface 4a and a flange 4b. The push knob 5 has a push surface 5a and a flange 5b. As shown in Fig. 2, plate-shaped light-shielding members 15 vertically protrude from a surface of the push knob 2 opposing the push knob 3, a surface of the push knob 2 opposing the push knob 5, a surface of the push knob 4 opposing the push knob 3, and a surface of the push knob 4 opposing the push knob 5, respectively. Recesses 16 into which ends of the lightshielding members 15 are inserted are formed in portions of 10 the push knob 3 opposing the respective light-shielding members 15 and portions of the push knob 5 opposing the respective light-shielding members 15. As shown in Fig. 1, when the ends of the respective light-shielding members 15 are inserted into the respective recesses 16, the push knobs 15 2, 3, 4, and 5 are disposed close to each other and to the rotary knob 1. In order to make it possible for the operator to see the functions of the respective push knobs 2, 3, 4, and 5, characters, pictorial characters, etc., which are illuminated by the exiting light 10a from the LEDs 10, may be 20 indicated on the push surfaces 2a, 3a, 4a, and 5a of the push knobs 2, 3, 4, and 5, respectively.

The case 6 is injection molded out of resin and into the shape of a box so that the case 6 can accommodate the wiring board 7, the rotation detector 8, the switch elements 9, the LEDs 10, and the light conductor 11.

25

The rotation detector 8 may be, for example, a rotary variable resistor or a rotary encoder. Its rotary shaft 8a

is connected to the rotary knob 1 through a required power transmission device such as a gear mechanism.

The switch elements 9 each comprise a tactile switch and a click rubber disposed on the wiring board 7, and have a 5 contact that is brought into electrical conduction with the wiring board and the click rubber by bending the click rubber. In order to make it possible to reliably operate the switch elements 9, the switch elements 9 are disposed at portions opposing the central portions of the respective push knobs 2, 3, 4, and 5. The switch elements 9 can be directly operated by the respective push knobs 2, 3, 4, and 5, or indirectly operated through a coupling member (not shown), which is called an actuator.

In order to make it possible for the LEDs 10 to

15 uniformly illuminate the area around the rotary knob 1, as shown in Figs. 1 and 2, the LEDs 10 are disposed at equal intervals around the light conductor 11.

The light conductor 11 is formed of a light-transmissive resin material and into an annular shape. As shown in Fig. 3, the light conductor 11 is disposed around a portion of the case 6 where the rotary knob 1 is disposed.

Since the lighted switch device of the embodiment comprises one rotary knob 1 and four push knobs 2, 3, 4, and 5, when any of the push knobs 2, 3, 4, and 5 are used for selecting functions, such as automatic-manual switching of a vehicle-installed air conditioner, in-vehicle-defrosting switching, temperature setting, and air volume setting, and when the rotary knob 1 is used for temperature adjustment and

air volume adjustment, it is possible to match the operational feel of the knobs 1 to 5 and the feel of selecting the respective functions and adjusting the functions. Therefore, the lighted switch device, which is used in a control section of the vehicle-installed air conditioner, provides good operational feel.

In the lighted switch device of the embodiment, the plate-shaped light-shielding members 15 protrude from a surface of the push knob 2 opposing the push knob 3, a surface of the push knob 2 opposing the push knob 5, a 10 surface of the push knob 4 opposing the push knob 3, and a surface of the push knob 4 opposing the push knob 5, The recesses 16 into which ends of the lightrespectively. shielding members 15 are inserted are formed in portions of the push knob 3 opposing the respective light-shielding 15 members 15 and portions of the push knob 5 opposing the respective light-shielding members 15. Therefore, the lightshielding members 15 only slightly appear at the surface of the lighted switch device, so that the design of the lighted 20 switch device can be improved. In addition, since each gap 12 between its associated pair of adjacent push knobs is completely closed by its associated light-shielding member 15, it is possible to prevent light from leaking into the gaps 12, so that the rotary knob 1 can be seen well. Further, since it is not necessary to form the light-shielding members at 25 the case 6, a gap 14 between the rotary knob 1 and the push knobs 2, 3, 4, and 5 can be reduced in size, so that, also for this reason, the design of the lighted switch device can

be improved, as a result of which the lighted switch device can be reduced in size. Further, since it is not necessary to form the light-shielding members at the case 6, it is possible to simplify and reduce the size of a die used for injection molding of the case 6, and, thus, to reduce the cost of the lighted switch device, which is a product.

Although, in the embodiment, the rotary knob 1 is used as a first operating knob and the push knobs 2, 3, 4, and 5 are used as second operating knobs, the gist of the present invention is not limited thereto, so that push knobs may be used for the first operating knobs and the second operating knobs.

10

15

Although, in the embodiment, the light-shielding members 15 are formed at the push knobs 2 and 4, and the recesses 16 are formed in the push knobs 3 and 5, the gist of the present invention is not limited thereto. Therefore, when the gaps 12 are shielded from light, it is possible to omit the recesses 16 formed in the push knobs 3 and 5.

Although, in the embodiment, the four push knobs 2, 3, 4, 20 and 5 are disposed around the rotary knob 1, the gist of the present invention is not limited thereto. Therefore, the number of push knobs disposed around the rotary knob 1 may be changed as required depending upon the purpose of use of the lighted switch device.
